

MARLET: Multi-Agent Retrieval for Learning-State-Aware Educational Tutoring

Anonymous Authors

Abstract—Large language models can generate fluent tutoring responses, but they need grounding that respects both instructional evidence and the learner’s current state. Classical retrieval-augmented generation (RAG) grounds generation through a fixed retrieve-then-read controller: the query is matched against a corpus, and the generator reads the returned passages. That design is often insufficient for tutoring, where the same surface question can require different evidence, scaffolding, or rubric constraints for different learners. We propose MARLET (Multi-Agent Retrieval for Learning-State-Aware Educational Tutoring), a framework that places a supervisory router, planner, diagnoser, rubric module, retriever, tutor, and critic around a fixed downstream tutor. The framework first builds a tutoring brief from the sample, inferred learning state, and answer criteria; retrieval is then invoked only when the route indicates that external evidence is needed. We validate the framework against classical RAG under matched backbones, corpus, reranker, and response budget on TutorEval and EduBench. MARLET improves fixed-tutor quality metrics over classical RAG while using fewer tokens; on EduBench it also reduces latency and backbone-call count. These results support the framework claim: for educational tutoring, grounding should be controlled by pedagogical state and task regime, not by the surface query alone.

I. Introduction

Large language models (LLMs) are increasingly used as educational tutors because they can generate explanations, diagnose errors, and provide feedback [1], [2]. However, an LLM tutor cannot rely only on parametric knowledge. Knowledge-grounded dialogue has long shown the value of external evidence [3]; educational responses similarly need grounding in textbook chapters, course notes, rubrics, worked examples, or learner profiles to avoid fluent but misaligned guidance.

Classical retrieval-augmented generation (RAG) has therefore become the default grounding mechanism [4]. In classical RAG, the query is embedded, the top- k most similar passages are retrieved, and the LLM generates a response conditioned on those passages. Thus, relevance depends heavily on retrieval quality and query representation [5].

Educational tutoring is more complex than factual question answering. A student’s question is often only a partial signal: the appropriate response may depend on level, goals, weak points, recent confusion, dialogue, and likely misconceptions. We call this the learner’s personalized learning state. Therefore, tutoring retrieval

must find evidence that is pedagogically appropriate for the learner, not merely topical.

One workaround is to append learner state, dialogue, grading criteria, and task constraints to the retrieval query. However, this shifts the burden onto one query embedding that must compress topic, level, misconception, instructional goal, and response constraints. This can blur search intent and return evidence that satisfies some needs while missing others.

Therefore, we propose MARLET (Multi-Agent Retrieval for Learning-State-Aware Educational Tutoring). Instead of letting the retriever act as the top-level controller, a supervisory router identifies the tutoring regime and decides whether retrieval is needed. A planner scopes search intent, a diagnoser summarizes visible learning state, and a rubric module states answer criteria before the fixed tutor writes.

The experiments validate the framework rather than present a model leaderboard. We compare with classical retrieve-then-read RAG while holding the backbone, corpus, reranker, response cap, tutor, and critic fixed. The baseline tests the standard design in which retrieval is driven before an explicit learner-state, plan, and rubric brief is constructed. Our validation on TutorEval and EduBench shows that the same tutor scores higher when fed context assembled by MARLET; on EduBench it also reduces latency and backbone calls.

Contributions. (i) We propose MARLET, a learning-state-aware multi-agent retrieval framework with a supervisory router, planner, diagnoser, rubric module, conditional retriever, tutor, and critic. (ii) We formalize the router and retrieval gate as transparent, training-free controls over learner state, rubric constraints, and external evidence. (iii) We validate against classical RAG on two educational benchmarks under shared backbone, corpus, reranker, and response budget.

II. Related Work

Classical RAG fixes retrieval as the first controller: the query is matched to passages, and generation conditions on the returned evidence [4]. Selective and corrective RAG methods improve this controller. Self-RAG learns when to retrieve, generate, and critique; CRAG evaluates retrieved documents and attempts correction when retrieval is unreliable; Adaptive-RAG and TARG vary retrieval behavior by query complexity or retrieval utility [6]–[9]. RAG diagnostics further emphasize separating retrieval, ranking, and generation errors [10]. These

methods address whether passages retrieved for a query are necessary, sufficient, or reliable, but they do not infer learner stage before retrieval, separate rubric constraints from topic evidence, or decide whether external passages are the right source of grounding for a tutoring decision.

Agentic RAG and multi-agent LLM systems move beyond a single retrieve-then-read step. ReAct, AutoGen, CAMEL, and MetaGPT show that tool use and role decomposition can improve complex task execution [11]–[14]. MA-RAG uses multiple agents for query disambiguation, evidence extraction, and answer synthesis on ambiguous or multi-hop QA tasks [15]. These systems demonstrate coordination benefits, but their roles are designed for general task execution or ambiguous question answering. They do not define pedagogical regimes, infer visible learner state, or bind the final response to rubric-style answer criteria, so the educational reason for retrieving, skipping retrieval, or prioritizing rubric context remains implicit.

Recent educational work shows that tutoring quality requires more than answer accuracy. AgentTutor builds multi-turn personalized learning with learner assessment and memory [2]; adaptivity studies show that LLM tutors are sensitive to omitted student-context features [16]; and AI-tutor evaluation emphasizes pedagogy, mistake diagnosis, guidance quality, and learner support [1], [17]–[20]. These works define tutoring requirements, but they do not formulate retrieval as learner-state-aware control: when to retrieve, what evidence to retrieve, and how much context to allocate to evidence rather than learner-state and rubric information.

III. Methodology

The proposed framework, MARLET, is a tutoring pipeline organized around a supervisory controller. For each sample, the controller reads the question, dialogue, context text, rubric items, and metadata, then assigns a pedagogical regime and decides which modules should run. The planner states the instructional goal and search intent, the diagnoser summarizes visible learning state, the rubric module lists answer criteria, and retrieval is invoked only when external evidence is needed. Fig. 1 sketches this pipeline.

The module boundaries come from observed benchmark patterns. TutorEval samples such as “Which is the fastest mode of heat transfer?” require the answer radiation, the explanation that no medium is required, and alignment with chapter evidence; a thermal-conductivity-unit sample requires isolating k and reasoning from SI units. These cases motivate a planner that narrows evidence search, a retriever that supplies chapter grounding, and a rubric module that preserves expected teaching points. EduBench supplies different signals: a personalized-learning sample describes a grade-five Chinese learner who likes folklore but struggles with pronunciation, while an emotional-support sample

TABLE I
Framework components and responsibilities.

Component	Responsibility
Supervisor	Assigns pedagogical regime and activates retrieval, rubric, and critic switches.
Planner	Converts the tutoring request into an operating plan and up to three scoped retrieval queries.
Diagnoser	Infers visible learning state from the prompt and dialogue, including level and likely misconceptions.
Rubric module	Summarizes explicit rubric items or default answer-quality criteria.
Retriever	Runs only when requested by the route or fallback gate, then reranks and packs evidence.
Tutor/Critic	Generates the final response and checks evidence markers, rubric coverage, and pedagogy.

describes anxiety about speaking in class. These motivate a diagnoser that captures visible learning state and affect before generation. EduBench grading and error-correction samples require a score, correction, and personalized feedback, motivating rubric constraints and the critic. Thus MARLET routes by grounding need rather than treating every sample as query-only retrieval.

The modules are also grounded in prior advantages: adaptive RAG treats retrieval as a decision [6], [8], [9]; ReAct/AutoGen motivate planning and role decomposition [11], [12]; tutoring research motivates learner assessment [2], [16]; tutoring benchmarks motivate rubric-style answer criteria [19], [20]; and long-context analyses plus MMR motivate compact relevance-diversity context packing [21], [22].

The design principle is simple: retrieve when external evidence is needed, and otherwise spend context on learner state and answer criteria. Validation keeps the tutor/critic backbone, corpus, reranker, packer, and response budget fixed so that the classical RAG comparison tests how context is assembled before the same tutor writes.

A. Supervisory Routing

The supervisor is the framework’s decision-making component. It estimates whether a sample primarily needs external evidence, pedagogical coordination, rubric feedback, planning, or dialogue-sensitive tutoring. The reported runs use transparent heuristics rather than a trained router. For a standardized benchmark sample x , the router first builds a normalized text blob $b(x)$ from the question, optional context, rubric text, and dialogue.

The first routing quantity is a cue-hit rate. For each cue phrase u , define $m(u, x) = 1$ if u appears in $b(x)$, and $m(u, x) = 0$ otherwise. For a cue family G , the router computes

$$\kappa_G(x) = \frac{\sum_{u \in G} m(u, x)}{|G|}, \quad (1)$$

where $|G|$ is the number of cue phrases in that family. Thus $\kappa_G(x)$ is just the fraction of cues that were observed: 0 means no cue matched, and 1 means every cue matched. The cue families are evidence (E), coordination (C), rubric (R), planning (P), and tutoring (T).

The cue-hit rate is then converted into a routing score:

$$s_j(x) = \min\{1, \max\{0, \kappa_j(x) + B_j(x) + P_j(d_x)\}\}, \quad (2)$$

where $j \in \{e, c, r, p, t\}$ indexes evidence, coordination, rubric, planning, and tutoring, and $\kappa_j(x)$ means the cue-hit rate for that cue family. The term $B_j(x)$ is a field bonus from visible sample structure: context or image fields increase the evidence score, rubric fields increase the rubric score, and longer dialogue increases the tutoring score. The term $P_j(d_x)$ is a dataset prior from the dataset label d_x ; for example, evidence-grounded datasets receive an evidence prior. The outer min/max only keeps the score between 0 and 1. These scores are not probabilities; they are transparent control signals used to decide which modules should run.

The router then assigns a pedagogical regime: lesson planning, rubric feedback, adaptive tutoring, or evidence-grounded reasoning. If the adapter supplies a regime hint, the supervisor uses it; otherwise it selects lesson planning when s_p is strongest and at least 0.42, rubric feedback when $s_r \geq \max\{s_t, 0.35\}$, adaptive tutoring when $s_t \geq 0.35$, and evidence-grounded reasoning otherwise. Retrieval is controlled by the binary gate

$$g(x) = \begin{cases} 1, & s_e(x) \geq 0.35 \text{ or regime}(x) = \text{EG}, \\ 0, & \text{otherwise.} \end{cases} \quad (3)$$

Here $s_e(x)$ is the evidence score and $\text{regime}(x) = \text{EG}$ means evidence-grounded reasoning. In words, retrieval is requested when the sample looks evidence-heavy or the regime itself is evidence-grounded. If $g(x) = 0$, the framework still builds the tutoring brief but skips retrieval. If no chunks have been retrieved and the evidence score is at least 0.45, one fallback retrieval pass is issued using the raw question. Thus the router constrains both how much pedagogical coordination to activate and whether the retriever should be used.

B. Specialist Agents and Shared Context

All implemented mechanisms operate over the same tutoring prompt, inferred learning state, rubric summary, retrieved evidence, and draft answer. The tutor and the critic are held constant across all implemented mechanisms: the tutor writes from the supplied context, and the route-controlled critic may revise the draft when the regime calls for adaptive tutoring. The only moving parts are the upstream context builders. In the reported configuration, planner, diagnoser, and rubric are deterministic heuristics. Their roles are asymmetric. The planner alone is retrieval-facing: it emits up to three deduplicated queries from the raw question, extracted key terms, dataset cueing, and the first rubric items. The diagnoser and rubric module are tutor-facing: they summarize transient learning state and answer criteria

for the tutor prompt, but they do not alter retriever scoring. In this release, learning state is inferred from the current question and dialogue rather than from a persistent profile store.

The tutor itself is the LLM-driven agent that produces the final response. It is dataset-aware but architecturally fixed: its prompt includes the dataset name, question, recent dialogue, inferred learning state, operating plan, rubric summary, and either retrieved evidence or inline benchmark context. It is instructed to be correct, pedagogically useful, concise, and to end with a next step or check-for-understanding when appropriate. Retrieved evidence must be cited with `[doc_id]` markers. EduBench consensus rows require a JSON object with a score, scoring details, and personalized feedback; TutorEval and the other tutoring-style profiles use instructional prose. This design isolates the effect of changing the retrieval context while leaving the downstream writer unchanged; personalization reaches retrieval mainly through planner query formulation, not through profile-aware reranking.

C. Hybrid Retrieval, Reranking, and Context Packing

The retrieval stack is intentionally lightweight and also follows the codebase exactly. The following equations are scoring rules, not learned models: a larger score means the chunk is ranked higher for the current query. For a query q and candidate chunk c , the hybrid index first computes

$$\text{score}_0 = 0.58 k_w + 0.17 k_{ch} + 0.25 k_\ell + \beta, \quad (4)$$

where all terms are computed for the current (q, c) pair. Here k_w is word-level TF-IDF similarity, k_{ch} is character 3–5 gram TF-IDF similarity, and k_ℓ is the similarity in the truncated-SVD latent space. The weights state how much the released retriever trusts each signal: word similarity contributes most, latent semantic similarity is second, and character similarity helps with spelling variants and short phrases. The query boost β adds 0.01 per overlapping title token and, in citation-seeking mode, an additional 0.025 for chunks whose source type is reference, lecture, or document. When multiple planner queries are issued, the retriever merges all returned candidates and deduplicates them by chunk identifier before reranking.

In the released paper configuration, no trained reranker is loaded, so the heuristic reranker score is

$$\text{score}_1 = 0.55 \text{score}_0 + 0.20 o_t + 0.10 o_h + 0.06 m_p + 0.05 o_n + 0.04 \rho, \quad (5)$$

where all terms are again computed for the current (q, c) pair. The variables o_t , o_h , m_p , and o_n denote token overlap, title overlap, exact phrase-match score, and numeric overlap, and ρ is a brevity prior. This reranker favors chunks that match the question text, title, exact phrases, and numbers while mildly preferring concise chunks. Once planner queries are merged, reranking

Fig. 1. Main framework of MARLET. The supervisory router scores the sample, assigns the pedagogical regime, and decides whether retrieval is needed before planner, diagnoser, and rubric modules assemble the tutoring brief.

remains question-centric and does not consume the learner summary directly.

Final context packing balances relevance against redundancy:

$$c^* = \arg \max_{c \in \mathcal{C} \setminus S} \lambda \text{score}_1(q, c) - (1 - \lambda) \max_{c' \in S} \text{overlap}(c, c'), \quad (6)$$

where c^* is the next selected chunk, $\mathcal{C}$ is the reranked candidate pool, S is the set of already packed chunks, and $\text{overlap}(c, c')$ is the redundancy term between two chunks. The first term rewards relevance to the query; the second term penalizes selecting another chunk that repeats content already in S . With $\lambda = 0.68$, a four-chunk cap, and a 6000-character context budget, this keeps the comparison focused on retrieval quality rather than on simply enlarging the context window.

D. Evaluation Protocol

Evaluation is dataset-aware, but the reported metrics are internal automatic proxies implemented in the released evaluator rather than official benchmark scoring scripts, following RAG work that separates retrieval, generation, and efficiency signals [10]. Token-F1 is the token-overlap F1 between the model answer and the benchmark reference answer. Rubric coverage is the fraction of rubric items the answer covers, using either near-verbatim phrase match or sufficiently strong token overlap anchored by a content-bearing token. Latency, total tokens, and backbone-call count capture inference

cost; backbone calls are the logged number of LLM requests needed for one sample.

For EduBench, we additionally report EB12D, the mean over 12 rubric-oriented signals spanning scenario adaptation, factual reasoning, and pedagogical application. Those signals reward output-format compliance, supportive but non-negative tone, relevance to the question, use of scenario elements from the sample, alignment with the benchmark score, domain-knowledge grounding, reasoning quality, error identification, clarity, motivational guidance, personalization, and higher-order prompting. We report EduAlign as $1 - |s(y) - \bar{s}|/100$, where y is the model’s JSON output, $s(y)$ is the numeric score extracted from it, and $\bar{s}$ is the benchmark reference score.

For TutorEval, we report tutor-hit as the mean key-point credit over the K expected teaching points, with full credit for explicit coverage, partial credit for moderate token overlap, and zero otherwise. We also track a chapter-grounding proxy by measuring whether the response stays aligned with retrieved evidence when retrieval is used, or with the inline chapter text otherwise. Concretely, EduBench is evaluated as a structured educational-judgment task, whereas TutorEval is evaluated as a chapter-grounded tutoring-response task. In the per-example evaluator outputs, off-profile metrics remain present as zeros; in the paper tables, benchmark-inapplicable columns are simply not shown. The released code also records a workload audit $U = T + 160Q_r +$

$90C_r + 240N_a + 30E_v$, where T is total tokens, Q_r retrieval queries, C_r retrieved chunks, N_a materialized agent outputs, and E_v trace events. This score is used only as an efficiency audit, not as a training objective. A retrieval-agnostic corpus-factuality check is supported when a compatible shared index is available, but the archived main comparison predates that audit, so we do not present it as a headline result here.

IV. Validation Experiments

We validate the framework on two public educational benchmarks. TutorEval [1] contains 834 expert-written science tutoring questions paired with long STEM chapters and teaching key points, so responses must explain, disambiguate, and stay chapter-grounded. EduBench [18] covers nine educational scenarios, including question answering, error correction, personalized support, emotional support, grading, teaching-material generation, and personalized content creation. Its rows contain prompts, scenario metadata, and reference model predictions; our adapter converts those references into consensus-style supervision through score statistics and rubric terms. For reporting, we use the 1562-example four-way EduBench intersection completed by all forced architectures.

The primary validation compares classical RAG with MARLET under matched Qwen3.5-4B infrastructure, reasoning budget 512, temperature 0.15, response cap 900, shared corpus, shared reranker, and fixed retrieval hyperparameters. Both systems run on the same benchmark samples. In classical RAG, retrieval is driven by the raw question before tutoring; the tutor then receives ordinary sample fields and retrieved chunks, but not the planner, diagnoser, or rubric brief. This is the intended contrast: the baseline tests retrieve-then-read grounding, while the proposed framework tests explicit context construction plus conditional retrieval.

The validation is fair at the infrastructure level but intentionally not identical at context construction: giving classical RAG the planner, diagnoser, and rubric outputs would convert it into the proposed framework, while withholding them from MARLET would remove the claimed contribution. We therefore report quality and resource outcomes together.

A. Framework Validation

Table II reports paired matched-sample comparisons with bootstrap confidence intervals and permutation p-values. On TutorEval, MARLET raises Token-F1, tutor-hit, and rubric coverage while using fewer tokens and fewer backbone calls; latency trends lower but is not reliable ($p=0.21$). Because the forced TutorEval harness computes route metadata before architecture forcing, the proposed framework retrieves on every TutorEval sample; this result tests whether planning, diagnosis, and rubric context help even when chapter evidence is always consulted.

TABLE II

Quality and 4090 resource summary. Quality is higher-better; runtime, tokens, and calls are lower-better.

Data	Metric	RAG	Ours	Δ
TutorEval	Token-F1	0.112	0.115	+0.004*
	TE hit	0.938	0.957	+0.019**
	Rubric	0.919	0.944	+0.026**
	Latency (s)	51.90	49.11	-2.79
	Tokens	3975	3490	-484***
	Calls	1.84	1.56	-0.28
EduBench	EB12D	0.367	0.398	+0.031***
	Rubric	0.705	0.891	+0.186***
	EduAlign	0.166	0.126	-0.040**
	Latency (s)	19.83	13.90	-5.92***
	Tokens	4020	2226	-1794***
	Calls	1.97	1.48	-0.49***

*** $p<10^{-4}$, ** $p<0.01$, * $p<0.05$. Runtime is mean wall-clock seconds per sample from paired 4B runs on the 4090 server.

B. Trade-offs and Ablations

For TutorEval, the 95% confidence intervals are [0.0002, 0.007] for Token-F1, [0.006, 0.032] for tutor-hit, and [0.006, 0.044] for rubric coverage. For EduBench, they are [0.027, 0.036] for EB12D, [0.174, 0.198] for rubric coverage, and [-0.069, -0.011] for EduAlign; cost intervals are [-6702, -5248] ms for latency, [-1847, -1741] tokens, and [-0.52, -0.46] calls. Classical RAG keeps a small EduAlign edge, but the frozen hybrid skips retrieval on every EduBench sample, so these prompts are usually better served by learner- and rubric-centered coordination than by external lookup.

The framework can use more modules than classical RAG, so resource cost must be reported. In these runs, scoped planner queries and the retrieval gate reduce token use; retrieval-free diagnostics remain unsuitable as main baselines for TutorEval because chapter evidence is required. Two 4B ablations on a shared TutorEval slice ($n=100$) further isolate the mechanism: forcing retrieval hurts Token-F1 (-0.003), tutor-hit (-0.015), and rubric coverage (-0.025), while disabling the shared critic shows that the main gain does not come from critic revision. On Qwen3.5-27B-FP8, TutorEval deltas collapse near zero but hybrid remains more efficient; EduBench 27B repeats the pattern with EB12D +0.032, rubric +0.210, tokens -1,861, and latency -22,070 ms.

These results clarify the intended use of MARLET: it is not a universal replacement for retrieval, but a controller for deciding what grounding a tutoring sample needs. Chapter-grounded samples still need evidence, whereas learner-profile, rubric, or scenario-heavy samples may be better served by learner-state and answer-criteria summaries than by mandatory topical retrieval.

V. Limitations

The study validates a framework rather than a final tutoring product. It reports automatic rather than human evaluation and is limited to two open-weight backbones, English-only data, benchmark outputs rather

than downstream learning gains, and visible learner-state inference from prompts and dialogue. Real deployment would require privacy safeguards, bias checks, data governance, and human instructional oversight.

VI. Conclusion

MARLET reframes grounding for educational tutoring as supervised context construction rather than query-only passage lookup. Under shared infrastructure, it improves fixed-tutor quality and efficiency over classical RAG, showing that learner state, rubric constraints, and conditional evidence should be coordinated before the tutor writes. Future work should compare against stronger controller-based RAG baselines, add human and multi-turn evaluation, and extend the router with learned calibration, profile-aware reranking, multilingual curricula, and privacy-preserving learner-state inference.
